

# Package ‘EcoIndR’

March 8, 2019

**Version** 1.5

**Title** Ecological Indicators

**Author** Cástor Guisande González

**Maintainer** Cástor Guisande González <castor@uvigo.es>

**Description** Calculates several indices, such as of diversity, fluctuation, etc., and they are used to estimate ecological indicators.

**License** GPL (>= 2)

**Encoding** latin1

**Depends** R (>= 3.1.1)

**Imports** rgeos

**Suggests** vegan, shape, Rarity, splancs, plotrix, FD, picante, sp, geoR, mgcv, raster, alphahull, sf, methods

**Repository** CRAN

DER	<i>DIFFERENTIATING SAMPLES USING RARITY, HETEROGENEITY, EVENNESS, TAXONOMIC, PHYLOGENETIC AND FUNCTIONAL DIVERSITY INDICES</i>
-----	--

---

## Description

An algorithm for differentiating samples on the basis of the rarity, heterogeneity, evenness, taxonomic/phylogenetic and functional diversity indices that better reflect the differences among assemblages.

## Usage

```
DER(data, Samples, Species, Taxon, TaxonFunc=NULL, TaxonPhyl=NULL,
pos=NULL, varSize="Richness", varColor="Rarity", Index=NULL, corr="sqrt",
palette= "heat.colors", size=c(1,5),digitsS=0, digitsC=2, ncolor=100,
transparency=1, references=TRUE, a=1.5, q=2.5, ResetPAR=TRUE, PAR=NULL,
dbFD=NULL, LEGENDS=NULL, TEXT=NULL, COLOR=c("#EEC591FF", "black", "grey50"),
file1="Diversity indices.csv", file2="Polar coordinates.csv",
file3="Indices and area of the polygon.csv", na="NA", dec=",", row.names=FALSE)
```

## Arguments

**data** Data file with the taxonomy, abundance of the species and functional traits (optional). The format of the file must be: an optional column with the position of labels' samples in the DER plot (blue column) in the same order as the variables with the species' abundance in the samples (red columns), the columns with the taxonomy of the species (as many as needed, green columns), the columns with the abundance of the species in each sample (red columns) and optionally the columns with the functional traits of the species. Each row is a unique species, genus, family, etc.

Pos	Class	Subclass	Superorder	Order	Family	Genus	Species	P1	M1	G1	P2
2	Eurotatoria	Monogononta	Pseudotrocha	Plolima	Asplanchnidae	Asplanchnopus	multiceps				
4	Eurotatoria	Monogononta	Pseudotrocha	Plolima	Euchlanidae	Beauchampella	eudactyloata				
3	Eurotatoria	Monogononta	Pseudotrocha	Plolima	Brachionidae	Brachionus	quadridentatus				
2	Eurotatoria	Monogononta	Pseudotrocha	Plolima	Notommatidae	Cephalodella	gibba	1			
3	Eurotatoria	Monogononta	Gnesiotrocha	Flosculariacea	Conochilidae	Conochilus	dossuarius				16
4	Eurotatoria	Monogononta	Pseudotrocha	Plolima	Euchlanidae	Diploechlanis	propatula				
4	Eurotatoria	Monogononta	Pseudotrocha	Plolima	Euchlanidae	Euchlanis	depidula	4	1	23	6
4	Eurotatoria	Monogononta	Pseudotrocha	Plolima	Euchlanidae	Euchlanis	sp1		3		
4	Eurotatoria	Monogononta	Pseudotrocha	Plolima	Brachionidae	Keratella	trochica	2	10		5

**Samples** Variables with the abundance of the species in each sample: sampling sites, dates, etc.

**Species** Variable with the name of the species (without including the genus). It may be other node of the phylogenetic tree, such as the genus, family, etc., for genus level phylogenies, family level phylogenies, etc.

**Taxon** Variables with the taxonomy of the species (taxonomic diversity), as many levels as needed but without including the variable with the node of the argument *Species*.

**TaxonFunc** Optionally variables with the functional traits (functional diversity).

**TaxonPhyl** Optionally the name of the RData file of the class phylo with the phylogeny. The file must be in the working directory.

**pos** Optionally it is possible to indicate a column with the position of labels' samples in the DER plot. It must be as many as the number of samples and in the same order than the variables described in the argument *Samples*. Values of 1, 2, 3

and 4, respectively indicate positions below, to the left of, above and to the right of the specified coordinates.

varSize	This variable defines the size of the bubble in the DER plot.
varColor	This variable defines the color gradient of the bubbles in the DER plot.
Index	The four/five indices used in the DER algorithm. If it is NULL the algorithm select one, index of rarity, one of heterogeneity, one of evenness one of taxonomy and one of the functional group (if functional traits are provided in the argument <i>TaxonFunc</i> ) that achieve a higher dispersion among samples in a polar coordinates system.
corr	Character string specifying the correction method to use, in the function <code>dbFD</code> , when the species-by-species distance matrix cannot be represented in a Euclidean space. Options are "sqrt" (default), "cailliez", "lingoes" or "none".
palette	The color gradient of the bubbles may be one of these palettes: "heat.colors", "terrain.colors", "gray.colors", "topo.colors" or "cm.colors", or any other option defined by the user.
size	Range of size of the bubbles. Two values: minimum and maximum size.
digitsS	Number of digits of the bubble size legend.
digitsC	Number of digits of the color legend.
ncolor	Gradient color of the color legend.
transparency	Transparency of the color gradient, from 0 to 1.
references	If it is TRUE the reference points are depicted on the DER plot.
a	Scale of Rényi diversity.
q	Scale of Tsallis diversity.
ResetPAR	If it is FALSE, the default condition of the function PAR of the package StatR is not placed and maintained those defined by the user in previous graphics.
PAR	It accesses the function PAR of the package StatR that allows to modify many different aspects of the graph.
dbFD	It accesses the function <code>dbFD</code> which allows to specify the arguments that calculates the functional diversity indices.
LEGENDS	It allows to modify the legend of the bubble size.
TEXT	It allows to modify the text of the labels in the bubbles.
COLOR	A vector with three values: color of the ellipse, color of the points in the legend of the size of the bubbles and color of the references points in the ellipse, respectively.
file1	CSV FILES. Filename with values of total abundance, richness and the rarity, heterogeneity, evenness, taxonomic, phylogenetic and functional diversity indices of each sample.
file2	CSV FILES. Filename with the polar coordinates of all samples considering the four/five selected indices.
file3	CSV FILES. Filename with the area of the convex hull ( $\alpha=6$ ) and Euclidean distance obtained in the polar coordinates system for all combinations of the indices.

na	CSV FILE. Text that is used in the cells without data.
dec	CSV FILE. It defines if the comma "," is used as decimal separator or the dot ".".
row.names	CSV FILE. Logical value that defines if identifiers are put in rows or a vector with a text for each of the rows.

## Details

### DER algorithm

The steps of DER algorithm are described below:

**1.** The function DER calculates the most often used indices (see below): a total of 39 indices that includes 2 of rarity, 14 of heterogeneity, 7 of evenness, 2 of taxonomic diversity, 8 of phylogenetic diversity and 6 of functional diversity. It is important to mention that the indices included in the groups of phylogenetic diversity and functional diversity, each explores a different facet of phylogenetic diversity (Kembel et al., 2010) and functional diversity (Laliberté et al., 2010), respectively.

#### Rarity indices

In the following equations  $S$  is the number of species (species richness),  $s$  is the number of samples,  $r_{ij}$  is the number of records of the species  $i$  in the sample  $j$ ,  $R$  is the total number of records considering all the species in all samples,  $Q_i$  is the occurrence of species  $i$ ,  $Q_{min}$  and  $Q_{max}$  are respectively the minimum and maximum occurrences in the species pool,  $r$  is the chosen rarity cutoff point (as a percentage of occurrence),  $w_i$  is the weight of the  $i$ th species in the assemblage,  $w_{min}$  and  $w_{max}$  the minimum and maximum weights respectively.

*Leroy* (Leroy et al., 2012; 2013)

$$w_i = \frac{1}{e^{(\frac{Q_i - Q_{min}}{rQ_{max}Q_{min}} * 0.97 + 1.05)^2}}$$

$$I_{RR} = \frac{\sum_{i=1}^S w_i}{\frac{\sum_{i=1}^S w_i}{S} - w_{min}} \cdot \frac{w_{max} - w_{min}}{w_{max} - w_{min}}$$

*Rarity* This index is a novel contribution of this package.

$$R = 1 - \frac{\sum_{i=1}^S \sum_{j=1}^s \frac{r_{ij}}{R}}{S}$$

#### Heterogeneity indices

In the following equations  $S$  is the number of species (species richness),  $p_i$  is the abundance's proportion of species  $i$ ,  $N$  is the total number of individuals in the sample,  $n_i$  is the number of individuals of the species  $i$ ,  $n_{max}$  is the number of individuals of the most abundant species,  $a$  and  $q$  are the orders of Rényi and Tsallis indices respectively and, finally, in Fisher's alpha the index is the  $\alpha$  parameter.

*log Shannon-Wiener (S.W.LOG2)* and *ln Shannon-Wiener (S.W)* (Wiener, 1939; 1948; 1949; Shannon, 1948; Shannon & Weaver, 1949). See Spellerger & Fedor (2013) for an explanation of the dual use of the terms Shannon-Wiener and Shannon-Weaver to refer to this diversity index.

$$H = - \sum_{i=1}^S p_i \log_2 p_i$$

$$H' = - \sum_{i=1}^S p_i \ln p_i$$

*Fisher's alpha* (Fisher et al., 1943)

$$\alpha x, \frac{\alpha x^2}{2}, \frac{\alpha x^3}{3}, \dots, \frac{\alpha x^n}{n}$$

*Simpson* (Simpson, 1949)

$$D_1 = 1 - \sum_{i=1}^S p_i^2$$

*Inverse Simpson (InvSimpson)* Williams (1964)

$$D_2 = \frac{1}{\sum_{i=1}^S p_i^2}$$

*Brillouin* (Brillouin, 1956)

$$H_B = \frac{\ln N! - \sum_{i=1}^S \ln n_i!}{N}$$

*Margalef* (Margalef, 1959)

$$D_{Mg} = \frac{(S-1)}{\ln N}$$

*Rényi entropy* (Rényi, 1961)

$$H_a = \frac{1}{(1-a)} \log \sum_{i=1}^S p_i^a$$

*Menhinick* (Menhinick, 1964)

$$D_{Mn} = \frac{S}{\sqrt{N}}$$

*McIntosh* (McIntosh, 1967)

$$D_{Mc} = \frac{N - \sqrt{\sum_{i=1}^S n_i^2}}{N - \sqrt{N}}$$

*Inverse Berger-Parker (InvB.P)* (Berger & Parker, 1970)

$$D_{BP} = \frac{1}{\frac{n_{max}}{N}}$$

*Hill numbers* (Hill, 1973)

Hill-Rényi

$$N_a = e^{H_a}$$

Hill-Tsallis

$$N_q = (1 - (q - 1)H_q)^{\frac{1}{(1-q)}}$$

where

a or q = 0 is species richness

a or q = 1 is Shannon's index (H')

a or q = 2 is Inverse Simpson's index ( $D_2$ )

a or q = Inf is Inverse Berger-Parker index ( $D_{BP}$ )

*Tsallis entropy* (Patil & Taillie, 1982; Tsallis, 1988)

$$H_q = \frac{1}{(q - 1)} \left( 1 - \sum_{i=1}^S p_i^q \right)$$

*Evenness indices*

Annotations of the equations as mentioned for heterogeneity indices.

*Simpson evenness (SimpsonE)* (Simpson, 1949)

$$E_{D1} = \frac{D_1}{S}$$

*Pielou (PielouE)* (Pielou, 1966)

$$J' = \frac{H'}{\ln S}$$

*McIntosh evenness (McIntoshE)* (McIntosh, 1967)

$$E_{Mc} = \frac{N - \sqrt{\sum_{i=1}^S n_i^2}}{N - \frac{N}{\sqrt{S}}}$$

*Hill evenness (HillE)* (Hill, 1973)

It is used Hill-Rényi numbers where in  $N_2$  the value of a = 2 and in  $N_1$  the value of a = 1

$$E_{2,1} = \frac{N_2}{N_1}$$

*Heip evenness (HeipE)* (Heip, 1974)

$$E_{Heip} = \frac{e^{H'} - 1}{S - 1}$$

*Camargo (CamargoE)* (Camargo, 1992)

$$E_{Camargo} = 1 - \sum_{i=1}^S \sum_{j=i'+1}^S \frac{|p_i - p_j|}{s}$$

*Smith and Wilson's Index (Evar)* (Smith and Wilson, 1996)

$$E_{var} = 1 - \left( \frac{2}{\pi} \right) \left( \arctan \left( \frac{\sum_{i=1}^S \left( \ln n_i - \frac{\sum_{j=1}^S n_j}{S} \right)^2}{S} \right) \right)$$

*Taxonomic diversity indices*

In the following equations summation goes over species  $i$  and  $j$ ,  $\omega$  are the taxonomic distances among taxa,  $x$  are species abundances, and  $n$  is the total abundance for a site.

*Taxonomic diversity (D)* (Clarke, 1995; 1998; 2001):

$$\Delta = \frac{\sum \sum_{i < j} \omega_{ij} x_i x_j}{n(n-1)/2}$$

*Taxonomic distinctness (Dstar)* (Clarke and Warwick, 1998):

$$\Delta^* = \frac{\sum \sum_{i < j} \omega_{ij} x_i x_j}{\sum \sum_{i < j} x_i x_j}$$

*Phylogenetic diversity indices*

Faith's phylogenetic diversity	Faith (1992)
Mean pairwise phylogenetic distance	Webb et al. (2008)
Mean nearest taxon distance	Webb et al. (2008)
Phylogenetic species richness	Helmus et al. (2007)
Phylogenetic species variability	Helmus et al. (2007)
Phylogenetic species evenness	Helmus et al. (2007)
Phylogenetic species clustering	Helmus et al. (2007)
Quadratic entropy	Rao (1982)

### Functional diversity indices

In the following equations  $S$  is the number of species, where  $d_{ij}$  is the difference between the  $i$ -th and  $j$ -th species,  $p_i$  is the abundance's proportion of the species  $i$ ,  $p_j$  is the abundance's proportion of the species  $j$ ,  $EW$  is weighted evenness,  $\text{dist}(i, j)$  is the Euclidean distance between species  $i$  and  $j$ , the species involved is branch  $l$ ,  $w_i$  is the relative abundance of the species  $i$ ,  $PEW_l$  is the partial weighted evenness,  $g_k$  are the coordinates of the center of gravity of the  $V$  species forming the vertices of the convex hull,  $x_{ik}$  is the coordinate of species  $i$  on trait  $k$ ,  $dG_i$  is the Euclidean distance of the center of gravity,  $\bar{dG}$  is the mean distance of the  $S$  species to the center of gravity,  $\Delta d$  is the sum of abundance-weighted deviances and  $\Delta|d|$  absolute abundance-weighted deviances.

Rao's quadratic entropy (Rao, 1982; Botta-Dukát, 2005):

$$Q = \sum_{i=1}^{S-1} \sum_{j=i+1}^{S-1} d_{ij} p_i p_j$$

$$d_{ij} = \sum_{k=1}^n \sum_{l=1}^n w_{kl} (X_{ik} - X_{jk})(X_{il} - X_{jl})$$

Functional group richness (FGR) Petchey and Gaston (2006)

Functional richness (FRic) is measured as the amount of functional space (convex hull volume) filled by the community (Villéger et al., 2008).

Functional evenness (FEve) (Villéger et al., 2008):

$$FEve = \frac{\sum_{l=1}^{S-1} \min(PEW_l, \frac{1}{S-1}) - \frac{1}{S-1}}{1 - \frac{1}{S-1}}$$

$$PEW_l = \frac{EW_l}{\sum_{l=1}^S EW_l} \quad EW_l = \frac{\text{dis}(i,j)}{w_i + w_j}$$

Functional divergence (FDiv) (Villéger et al., 2008):

$$FDiv = \frac{\Delta d + \bar{dG}}{\Delta|d| + \bar{dG}}$$

$$\Delta|d| = \sum_{i=1}^S w_i |dG_i - \bar{dG}| \quad \Delta d = \sum_{i=1}^S w_i (dG_i - \bar{dG})$$

$$\bar{dG} = \frac{1}{S} \sum_{i=1}^S dG_i \quad dG_i = \sqrt{\sum_{k=1}^T (x_{ik} - g_k)^2} \quad g_k = \frac{1}{V} \sum_{i=1}^V x_{ik}$$

*Functional dispersion (FDis)* (Laliberté and Legendre, 2010):

$$FDis = \frac{\sum a_j z_j}{\sum a_j} \quad c = \frac{\sum a_j x_{ij}}{\sum a_j}$$

2. Each index is transformed to a scale range between 0 and 1 for all samples with the following equation:

$$\frac{(index\ of\ the\ sample - min)}{(max - min)}$$

where *min* and *max* are the minimum and maximum values of the index considering all samples, respectively.

3. With the standardized values of the indices, the algorithm calculates the polar coordinates of all samples with all possible combinations among all groups of indices. Therefore, in each combination an index of each group of rarity, heterogeneity (species richness is included in this group), evenness, taxonomic/ phylogenetic diversity and functional diversity (if it is included functional traits in the analysis) is used for calculating the polar coordinates of all samples. In the group of taxonomic/phylogenetic diversity the user must use either taxonomy or a phylogenetic tree, so either taxonomic diversity or phylogenetic diversity indices are used in the algorithm. The X and Y polar coordinates for each sample are estimated using the following equations:

$$X = \sum_{i=1}^4 |z_j| \cos(\alpha) \quad Y = \sum_{i=1}^4 |z_j| \sin(\alpha)$$

where *z* is the standardized value of the index *j* of the four groups considered.

Each index is assigned an angle ( $\alpha$ ). Degrees to radians angle conversion is carried out assuming that 1 degree = 0.0174532925 radians.

4. With the polar coordinates of the samples obtained for each combination, it is calculated the convex hull (alpha = 6) and the mean Euclidean distance, and the values are saved in a file.

5. The algorithm selects the combination of indices with the highest value of the mean between convex hull and mean Euclidean distance among samples, therefore priority is given to maximize dispersion among samples (see Fig. 1). The polar coordinates of the selected combination are depicted on a diagram, where it is possible to see the differences in rarity, heterogeneity, evenness and taxonomic/phylogenetic diversity and/or functional diversity (if it is included) among assemblages.

6. Finally, DER function allows the user to select the four/five indices to be used in the diagram, so the algorithm of selecting the combination with the maximum dispersion among samples is not applied.

## FUNCTIONS

The index Fisher alpha was estimated with the function [fisher.alpha](#), the index Rényi with the function [renyi](#), the index Tsallis with the function [tsallis](#), the taxonomic diversity and taxonomic distinctness with the functions [taxa2dist](#) and [taxondive](#), all of them of the package [vegan](#) (Oksanen et al., 2016). The ellipse is depicted with the function [plotellipse](#) of the package [shape](#) (Soetaert,

2016). The convex hull (alpha=6) was calculated with the function `areapl` of the package `splancs` (Bivand et al., 2016). The color legend of DER plot was depicted with the function `color.legend` of the package `plotrix` (Lemon et al., 2016). The rarity index of Leroy was calculated with the functions `rWeights` and `Irr`, both of the package `Rarity` (Leroy et al., 2012; 2103; Leroy, 2016). The functional diversity indices were calculated with the function `dbFD` of the package `FD` (Laliberté et al., 2015). The phylogenetic indices were calculated with the functions `psv`, `psr`, `pse`, `pse`, `raoD`, `mntd`, `mpd` and `pd` of the package `picante` (Kembel et al. 2010 2016)

### EXAMPLE

The example without functional diversity is a dataset with the abundance of rotifers species in ponds (see table 1 in Mazuelos et al., 1993). In the argument *Index* were selected Rarity, Menhinick, McIntoshE and Dstar, which are the indices selected by the algorithm when *Index=NULL* (default option). The sample G3.1 had the lowest values of the indices of rarity, heterogeneity, evenness and taxonomic diversity and the pond I3.1 the highest values for all indices.

### Value

It is depicted a plot of polar coordinates estimated with the rarity, heterogeneity, evenness, taxonomic/phylogenetic and functional diversity indices, CSV files are saved with all the indices, the polar coordinates estimated with the indices specified in the argument *Index* or estimated by the algorithm, and the area of the convex hull and mean Euclidean distance obtained in the polar coordinates system for all combinations of the indices.

## Arguments

data	Data file (CSV, RData or Excel) with the latitudes and longitudes and the values of the environmental variables. This file may also include the latitudes and longitudes of the polygons. Each polygon must be separated by a blank row.
var	Variable with the values of the environmental variable.
dataLat	Variable with the latitudes of the environmental variable.
dataLon	Variable with the longitudes of the environmental variable.
polyLat	If the geographic coordinates of the polygons are in the same file than the data of the variable, here it is indicated the variable with the latitudes of the polygons.

polyLon	If the geographic coordinates of the polygons are in the same file than the data of the variable, here it is indicated the variable with the latitudes of the polygons.
zonedata	If the latitude and longitude of the data are in UTM, it is necessary to specify the variable with the zone of each pair of coordinates in this argument.
zonepoly	If the latitude and longitude of the polygons are in UTM, it is necessary to specify the variable with the zone of each pair of coordinates in this argument.
convex	If it is TRUE, it is considered as polygon the alpha shape of the distribution of the variable. This option is useful if the variable is for instance the abundance of a species, so the spatial interpolation is performed considering the limits of the distribution of the species.
alpha	Alpha value of the alpha shape.
ASC	ASC file with the values of the variable. It is not necessary to specify the latitude and longitude of the variable, but it is mandatory to specify the polygon (in the argument <i>data</i> , <i>shape</i> or <i>Area</i> ).
shape	It is possible to use a shape file for importing the coordinates of the polygons. In this case, it is not necessary to specify the latitude and longitude of the polygons in the arguments <i>polyLat</i> and <i>polyLon</i> .
shapenames	Variable in the shapefile with the names of the polygons.
Area	Only if using RWizard ( <a href="http://www.ipez.es/RWizard">http://www.ipez.es/RWizard</a> ). It is also possible to use the polygons available in RWizard of administrative areas and river basins. A character with the name of the administrative area or a vector with several administrative areas (countries, regions, etc.) or river basins. In this case, it is not necessary to specify the latitude and longitude of the polygons in the arguments <i>polyLat</i> and <i>polyLon</i> . If it is "World" the entire world is plotted.
validation	Percentage of cases used from original data for validation. These data are not used for the estimation of the model and they are just used for evaluating the accuracy of the model (see details). If it is zero, all data are used for estimating the accuracy measures. If there are many data, a way for shortening the running time is to increase the number of data for validation, so reducing the number of data used for estimating the models.
type.krige	Type of kriging to be performed. Options are simple "SK" or ordinary kriging "OK". Kriging with external trend and universal kriging can be defined setting <code>type.krige="OK"</code> and specifying the trend model using the arguments <i>trend.d</i> and <i>trend.l</i> .
trend.d	It specifies the trend (covariate) values at the data locations (see function <a href="#">krige.conv</a> of the package <code>geoR</code> ).
trend.l	It specifies the trend (covariate) values at prediction locations. It must be of the same type as for <i>trend.d</i> . Only used if prediction locations are provided in the argument <i>locations</i> (see function <a href="#">krige.conv</a> of the package <code>geoR</code> ).
model	If it is "AUTO", the algorithm tries to find the model with the highest accuracy measures (see details). It is also possible to select one or several of the following models: "exponential", "matern", "gaussian", "spherical", "circular", "cubic", "wave", "power", "linear", "cauchy", "gneiting", "powered.exponential", and/or "pure.nugget".

minimisation	Minimization function used to estimate the parameters of the model fitted to the semivariogram. The options are "optim", "nlm" or "nls" (see function <a href="#">variofit</a> of the package <code>geoR</code> ).
weights	Type weights used in the loss function when fitting the model to the semivariogram. The options are "npairs", "cressie" or "equal" (see the function <a href="#">variofit</a> of the package <code>geoR</code> ).
maxdist	Maximum distance in the semivariogram. If it is NULL, it is half of the maximum distance of the semivariogram.
nugget,sill,range	The value of the nugget variance parameter $\tau^2$ , fixed value of the sill parameter ( $\sigma^2$ ) and fixed value of the range parameter ( $\phi$ ). If they are NULL (default) the algorithm tries to find the optimal values for each of the models specified in the argument <i>model</i> .
kappa	One numerical value required for the following models: "matern", "cauchy", "gneiting.matern" and "powered.exponential", and two values for the model "gencauchy". If they are NULL (default) the algorithm tries to find the optimal values for each of the models specified in the argument <i>model</i> .
beta	Numerical value of the mean (vector) parameter. Only used if type.krige="SK". If it is NULL, it is automatically estimated by the algorithm.
jitter	It may be one of these three options: "NO" means no action, "jitter" means that jitters duplicated coordinates of the environmental variable, and "mean" means that the mean of the environmental variable is estimated for those duplicated coordinates.
maxjitter	Maximum jittering distance in decimal degrees.
direction	A vector with values of 4 angles, indicating the directions for which the variograms will be computed. Default corresponds to c(0,45,90,135 (degrees).
inside	If it is TRUE only those geographic coordinates of the environmental variables inside the polygons are considered for the estimation of the model.
error	If it is TRUE, a contour map with the standard errors is depicted.
ResetPAR	If it is FALSE, the default condition of the function PAR is not placed and maintained those defined by the user in previous graphics.
PAR	It accesses the function PAR that allows to modify many different aspects of the graph.
BOXPLOT	It allows to specify the characteristics of the function <a href="#">boxplot</a> .
OUTLINE	If it is TRUE, the outliers are shown in the boxplot.
XLABP, YLABP	Legends of X and Y axes of the plot with the relationship between observed and predicted values of the model.
XLAB, YLAB	Legends of X and Y axes of the contour plot with the spatial interpolation.
XLABB, YLABB	Legends of X and Y axes of the boxplot .
MAIN	Main title of the contour plot with the spatial interpolation.
XLIM, YLIM, ZLIM	Limits of the contour plot.
COLOR	Palette of colours or a vector with the colours of the contour plot.

COLORC	Colour of the lines in the contour plot.
COLORB	Vector with the colours of the models or just one colour for all models of the boxplot.
COLORM	Colour of the administrative areas and river basins, if any area has been specified in the argument <i>Area</i> and <i>convexhull=TRUE</i> .
NLEVELS	Numeric vector of levels at which to draw contour lines.
LABCEX	Size of the text in the contour lines.
contour	If it is TRUE, the contour lines are depicted in the contour plot.
breaks	Number of breakpoints of the colour legend in the contour plot.
ndigits	Number of decimals in the legend of the colour scale in the contour plot.
x1,xr	The left and right limits of the colour legend considering the X axis of the contour plot.
pro	If it is TRUE, an automatic calculation is made in order to correct the aspect ratio y/x along latitude.
cell	Cell size in decimal degrees of the grid inside the polygons with the predictions of the model. If it is NULL, it is automatically estimated according to the limits of the polygons. To select an appropriate cell size according to the polygon size is important for shortening the running time.
file1	CSV FILES. Filename with the predictions of the models.
file2	CSV FILES. Filename with the predictions inside the polygons.
file3	CSV FILES. Filename with accuracy measures of the models.
file4	CSV FILES. Filename with values of the semivariogram.
file5	CSV FILES. Filename with standard errors of the predictions.
file6	TXT FILE. Model selected with indication of the accuracy measures.
na	CSV FILE. Text that is used in the cells without data.
dec	CSV FILE. It defines if the comma "," is used as decimal separator or the dot ".".
row.names	CSV FILE. Logical value that defines if identifiers are put in rows or a vector with a text for each of the rows.

## Details

### SINENVAP algorithm

The aim of this algorithm is to select a model, from a set of different models, with the nugget variance parameter  $\tau^2$ , fixed value of the sill parameter ( $\sigma^2$ ) and fixed value of the range parameter ( $\phi$ ), as close as possible to those values that generates an optimal spatial interpolation, and to validate the predictions obtained. The model and parameters selected by the algorithm may be utilized by users as references, or to make modifications for spatial interpolation prediction improvement.

The algorithm uses the package geoR (Ribeiro and Diggle, 2001; 2018) to estimate simple, ordinary, and universal kriging. The corresponding algorithm is detailed below.

#### 1. Data with variable and polygon coordinates.

The algorithm must be supplied with variable values (argument *var*), latitude and longitude for each datum (arguments *dataLat* and *dataLon*), and polygon coordinates (arguments *polyLat* and *polyLon*), for the estimation of spatial interpolation.

Variable and polygon latitudes and longitudes may be in either decimal or UTM form. If they are in UTM form, a column with the zone of each coordinate in the *zonedata* and *zonepoly* arguments must be added for variable and polygon coordinates, respectively. Polygon variables and coordinates are not required to be in the same units. Therefore, variables may be in decimal form, and polygons in UTM form, vice versa, or both may be in the same units.

Variable and polygon information data may be in CSV, EXCEL, or RData files. ASC files (argument *ASC*) may also be used for the variable, but in this case, it is not necessary to provide latitude or longitude information for each datum in the *dataLat* and *dataLon* arguments. Polygon coordinates may be in the same file as variable data in CSV, EXCEL, or RData files.

If RWizard is used, any of the administrative areas available in RWizard may be chosen as polygons in the *Area* argument: countries, departments, provinces, etc. River basins may also be used as polygons, in the database available in RWizard (González-Vilas et al., 2015).

Shape files may be used to import polygon coordinates with the *shape* argument. If a shape file or the polygons available in RWizard are used, coordinate specification is unnecessary in *polyLat* and *emphpolyLon* arguments.

Finally, if the argument *convex=TRUE*, the alpha shape distribution is considered to be a polygon. This last option is useful when the variable is, for instance, the abundance of a species, such that spatial interpolation is performed considering the limits of species distribution. If *convex=TRUE*, the specification of information in *polyLat* and *polyLon* arguments is unnecessary.

## 2. Algorithm design.

Algorithm steps are described as follows:

1. If the argument *inside=TRUE* (default option), based on all variable data available, only those data inside the polygons are used to estimate spatial interpolation. If the argument *inside=FALSE*, all available variable data are used.
2. Duplicated coordinates may be treated in two ways: with the application of a jitter function (default) or with estimation of the mean value of the variable for duplicated coordinates.
3. Spatial interpolation estimates the values on a grid. Therefore, it is necessary to first create a grid with a fixed cell size, in which the spatial interpolation will be estimated. If the argument *cell=NULL* (default), the algorithm estimates the optimal grid cell size, in accordance with polygon size. The output TXT provides information about the cell size chosen. The user may specify different cell sizes. Appropriate cell size selection, in accordance with polygon size, shortens running time.
4. Only those points in polygons are selected from the grid created, for the spatial interpolation prediction.
5. By the default *validation=30*, which means that 30% of variable data are not used in the spatial interpolation model. However, they are employed to test the model. If *validation=0*, all data are used in the model, and model validation is performed with all data. If validation is higher than zero, because validation data are randomly selected, spatial interpolation values may vary each time the script is implemented.
6. In order to test the model, the grid coordinates nearest to data coordinates are selected. Cross validation is performed by comparing variable data reserved for validation (see step 5) to spatial in-

terpolation predictions on the grid, so as to verify which coordinates are nearest to the data reserved for validation.

7. Next, the semivariogram is depicted (Fig. 1). If the argument *maxdist=NULL* (default), it is considered to be half of the maximum semivariogram distance for performing the models.

8. Any of the following models may be implemented: cauchy, circular, cubic, exponential, gaussian, gneiting, linear, matern, power, powered.exponential, pure.nugget, spherical, or wave. If *model="AUTO"*, all models are tested, with the exception of matern. The *variofit* function in the *geoR* package is used to find the nugget, range, and sill for each model. The data reserved for validation are compared to model predictions, and seven accuracy measures, described in the following section, are used to decide which model made the best prediction. The model that made the best prediction is chosen by the algorithm to depict variable spatial interpolation in the selected polygons.

### 3. Accuracy measures.

The following accuracy measures are used in the algorithm, so as to compare and evaluate model predictions, where  $n$  is the number of observations, and  $P$  and  $O$  are the predicted and observed values for each  $i$  datum, respectively.

The measures catalogued as "normalized" are adapted to reflect values of 1 when the model is most efficient (i.e., predictions are the same as observed values). Thus, in all accuracy measures used in the algorithm, the maximum value is 1. This indicates a model with maximum predictive power. Various measures were utilized to obtain improved evaluation framework (i.e. consideration of a group of skill scores that show different result characteristics) (see Li and Head, 2011).

3.1. *r-squared* ( $r^2$ ). This is the square of the Pearson correlation coefficient ( $r$ ) between the predictions of the interpolation model and the observed values. It ranges from 0 to 1.

$$r = \frac{\sum_{i=1}^n [(O_i - \bar{O})(P_i - \bar{P})]}{\sqrt{\sum_{i=1}^n (O_i - \bar{O})^2 \sum_{i=1}^n (P_i - \bar{P})^2}}$$

3.2. *Normalized mean absolute error (NMAE)*. This is a measure of the average error between predictions and observed values. It ranges from  $-\infty$  to 1.

$$NMAE = 1 - \frac{\sum_{i=1}^n |P_i - O_i|}{\sum_{i=1}^n O_i}$$

3.3. *Normalized root mean square error (NRMSE)*. This measure shows the distribution error variability. It ranges from  $-\infty$  to 1.

$$NRMSE = 1 - \sqrt{\frac{\sum_{i=1}^n (P_i - O_i)^2}{\sum_{i=1}^n O_i}}$$

**3.4. Nash-Sutcliffe coefficient ( $E$ ).** Nash-Sutcliffe efficiencies may range from  $-\infty$  to 1 (Nash & Sutcliffe, 1970). An efficiency of 1 ( $E = 1$ ) corresponds to a perfect match between model and observations. An efficiency of 0 indicates that the model predictions are as accurate as the mean of the observed data, whereas an efficiency less than zero ( $-\infty < E < 0$ ) occurs when the observed mean is a better predictor than the model.

$$E = 1 - \frac{\sum_{i=1}^n (O_i - P_i)^2}{\sum_{i=1}^n (O_i - \bar{O})^2}$$

**3.5. Index of agreement ( $d$ ).** It was developed by Willmott (1981) as a standardized measure of the degree of model prediction error and varies between 0 and 1.

$$d = 1 - \frac{\sum_{i=1}^n (O_i - P_i)^2}{\sum_{i=1}^n (|P_i - \bar{O}| + |O_i - \bar{O}|)^2}$$

**3.6. Normalized relative mean absolute error (NRMAE).** This is a modification of a measure developed by Li and Head (2011), whose maximum value is 1. According to the authors, this measure removes the effect of unit/scale and is not sensitive to changes in unit/scale. It ranges from  $-\infty$  to 1.

$$NRMAE = 1 - \frac{\sum_{i=1}^n \frac{|P_i - O_i|}{O_i} * 100}{\sum_{i=1}^n O_i}$$

**3.7. Normalized relative root mean square error (NRRMSE).** This is a modification of a measure developed by Li and Head (2011), whose maximum value is 1. It ranges from 0 to 1.

$$NRRMSE = 1 - \left[ \frac{\sum_{i=1}^n \left( \frac{|P_i - O_i|}{O_i} \right)^2}{\sum_{i=1}^n O_i} \right]^{\frac{1}{2}} * 100$$

## FUNCTIONS

Spatial interpolation, using simple, ordinary, and universal kriging, is performed with `as.geodata`, `variofit`, `krige.conv` and `krige.control` functions, as well as the jitter of points with the `jitterDupCoords` function, all of which are from the `geoR` package (Ribeiro and Diggle, 2001; 2018).

The ASC files are loaded with the raster function from the raster package (Hijmans et al., 2018).

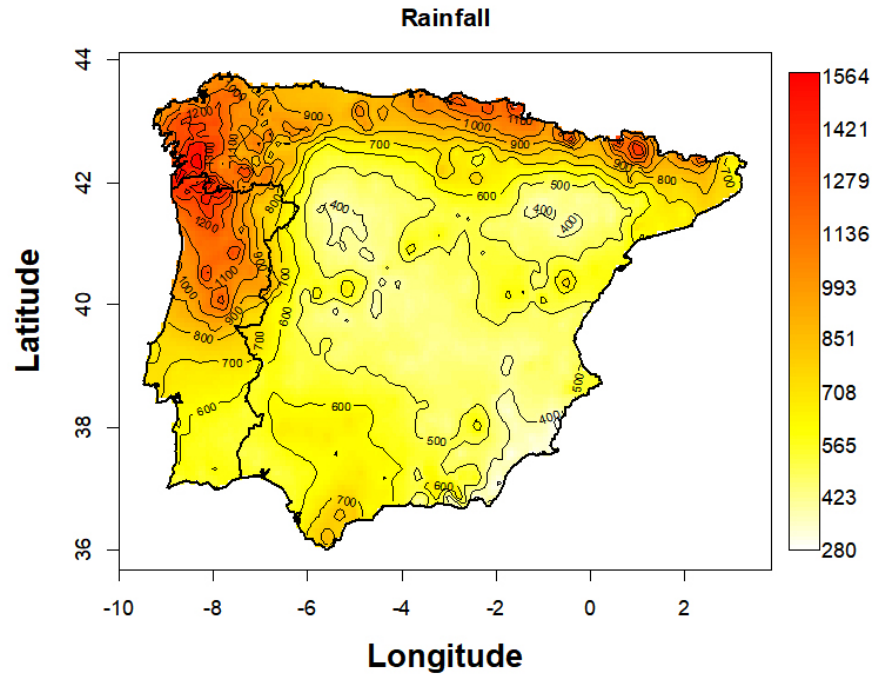

Points inside polygons are estimated with the `in.out` function from the `mgcv` package (Wood, 2018).

The `sp` package (Pebesma and Bivand, 2005; Pebesma et al., 2018) is used to process shape files.

The BreuschPagan test is performed with the `bptest` function from the `lmtest` package (Zeileis and Hothorn, 2002; Hothorn et al., 2018).

The color scale is depicted with the `color.legend` function from the `plotrix` package (Lemon, 2006; Lemon et al., 2018).

**EXAMPLE** The figure shows the contour map of the spatial interpolation of the example 1, the rainfall in the Iberian Peninsula.

### Value

It is obtained:

1. A CSV file, called "Predictions data.CSV" by default, contains model data and predictions. If *validation=0*, the observed data are from the original dataset. Predicted values are those points inside the polygon, which are, spatially, the nearest neighbors to the observed data.
2. A CSV file, "Predictions polygon.CSV" by default, contains predictions for inside polygons.
3. A CSV file, called "Accuracy measures.CSV" by default, contains the values of the seven accuracy measures shown above, for all models.
4. A CSV file, called "Semivariogram.CSV" by default, contains semivariogram values.
5. A CSV file, called "Standard errors.CSV" by default, contains the standard prediction errors.
6. A TXT file called "Model selected.TXT" by default, contains the full details of the model selected by the algorithm.
7. A plot of the semivariogram, with the values used in the models, is depicted in green. Application of the maximum distance specified in the *maxdist* argument, and the points in red, yield a semivariogram without distance limitations.
8. The directional variogram in four directions.
9. A plot with the relationship between observed and predicted values. As mentioned above, the observed values may be either randomly selected values or those from the original dataset. If

`validation=0`, the observed data are from the original dataset. Predicted values are those points inside the polygon, which are, spatially, the nearest neighbors to the observed data.

10. If the argument `model` is "AUTO", or there is more than one model, a boxplot is depicted with the median value of the seven accuracy measures from each model.

11. The contour plot with the spatial interpolation predictions of the selected model, i.e., the model with the highest accuracy measures mean.

12. If the argument `error=TRUE`, the contour plot is depicted with the selected model's standard errors.

The 3 bioclimatic variables of WorldClim at a resolution of five arc-minutes (Hijmans et al., 2005) BIO8 (Mean Temperature of Wettest Quarter), BIO12 (Annual Precipitation) and BIO15 (Precipitation Seasonality, Coefficient of Variation) were used to generate the distribution of the virtual species by using the virtualspecies R package (Leroy et al. 2016; 2018). The limits were from -5° to 6° in latitude, and from 44° to 49°. Subsequently, 50% of the data were randomly selected, in

order to simulate a random sampling of the species. The final continuous suitability maps obtained in this way were scaled between 0 and 1.
